BPL IEC validation

Author: Jan Peter Axelsson

Here I try to reproduce somre results from Jonas Månssons master thesis report "Control of chromatography comlumn in production scale", TFRT-5599.

The interaction withe the model has changed slightly so that linear flow rate LF = F/area is used. The column volume is now specified in terms of (cross-section) area times height. Thus by changing area the scale up works fine and what you do in practice. Further the time unit changed from seconds to minutes.

The model has 5 states as listed below, 3 states in liquid mobile phase and 2 states for the gel for bound proteins. In a few of Jonas figures also bound ions of the buffer are plotted but I do not do that. Bound ions of the buffer can be calculated from the difference of total binding capaciety \$Q_{av}\$ and bound protein and bound protein antagonist, see section 5.1 in the report.

The molecular weights listed below are not used in the simulations. They just give typical values and the molecular weight for bound protein and antagonist protein is just arbitrary here.

Parameters of the model in general as well as time scale are all arbitrary and focus is on qualitative aspects of the model.

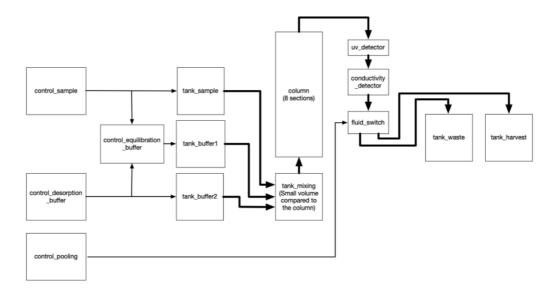

The height of the column is 20 cm which is a common size in the industry.

Note that both disp() and describe() takes values from the last simulation and the command process_diagram() brings up the main configuration

Brief information about a command by help(), eg help(simu)
Key system information is listed with the command system_info()

```
In [2]: plt.rcParams['figure.figsize'] = [30/2.54, 24/2.54]
In [3]: # The process diagram is made outside Modelica to illustrate the configuration process_diagram()
```

No processDiagram.png file in the FMU, but try the file on disk.

```
In [4]: describe('chromatography'); print(); #describe('liquidphase')
```

Ion exchange chromatorgraphy controlled with varying salt-concentration. The pH is kept constant.

Loading or adsorption

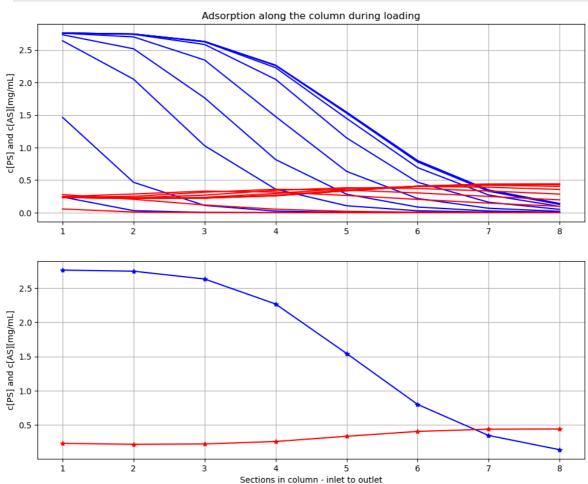

The parameter notation and values are the same as in the referred report. However the flow rate is here denoted F while q in the report. The column is diveded in n=8 sections and set at compilation time. The values are arbitrarly chosen in the report and the focus is on qualitative aspects of the model.

The simplified model describe only the column in terms of volume and does not distinguish a high column with a small diameter from a lower with larger diameter.

The parameters k1, k2, k3, k4 and Q_av are given relative volume and with increased column volume a larger capacity is thus obtained.

```
In [5]:
        # Loading of the column - try to reproduce Jonas figure 13.
        newplot(title='Adsorption along the column during loading', plotType='Loading')
        # Sample
        par(P_in=1.0, A_in=1.0, E_in=0)
        # Column properties
        par(k1=0.3, k2=0.05, k3=0.05, k4=0.3, Q_av=3.0)
        par(height=20, diameter=0.714)
        par(x m=0.3)
        # Operation
        par(E_in_desorption_buffer=8)
        par(LFR=12)
        par(scale_volume=False)
        par(start_adsorption=0, stop_adsorption=50)
        par(start desorption=150, stationary desorption=450)
        par(start_pooling=220, stop_pooling=450)
```

The results are the same af Figure 13 in [1].

```
In [6]: # We just check that we had the same volume flow rate as Jonas
describe_general('V', decimals=3)
```

Column volume total - derived : 8.008 [mL]

parLoc = parLocation['V'] par_var = model_description.modelVariables for k in range(len(par_var)): if par_var[k].name == parLoc: try: if par_var[k].name in start_values.keys(): value = start_values[par_var[k].name] elif par_var[k].variability in ['constant', 'fixed']:

value = float(par_var[k].start)

elif par_var[k].variability == 'continuous': try: timeSeries = sim_res[par_var[k].name] value = timeSeries[-1] except (AttributeError, ValueError): value = None print('Variable not logged') else: value = None except NameError: print('Error: Information available after first simution') value = None print(value)

```
In [7]: par_var = model_description.modelVariables
In [8]: for k in range(50):
    print(par_var[k].name)
```

                                                                   0.5
                                                                   0.0
                         20
                                         60
                                                  80
                                                          100
                                                                              2
                                  Time [min]
                                                                                Section in column - inlet to outlet
```

To the left the inlet loading over time. To the right upper concentration along the column at different times and in steady states finally To the right lower concentrations along the column in steady state.

We see that a shorter time and then less material makes less of the column capacity used.

Note that the flow through the column is constant despite change from sample to just buffer 1, and shown in how the volume of the waste tank increase with time.

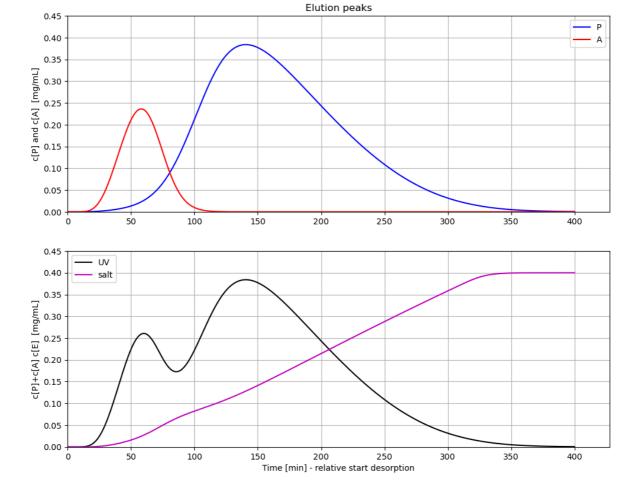

Elution or desorption

```
In [14]: # Elution of the column
    newplot(title='Elution peaks', plotType='Elution')

# Sample
    par(P_in=1, A_in=1.0, E_in=0)

# Operation
    par(E_in_desorption_buffer=8)
    par(LFR=12.0, start_adsorption=0, stop_adsorption=50, start_desorption=150, stat

# Simulation
    simu(550)
```

The results are the same af Figure 14 in [1].

The upper diagrams shows the column outlet concentrations of P and A over time.

The lower diagram shows the sum (or possibly the UV signal) at column outlet as well as the salt concentration. We have some separation between the two peaks.

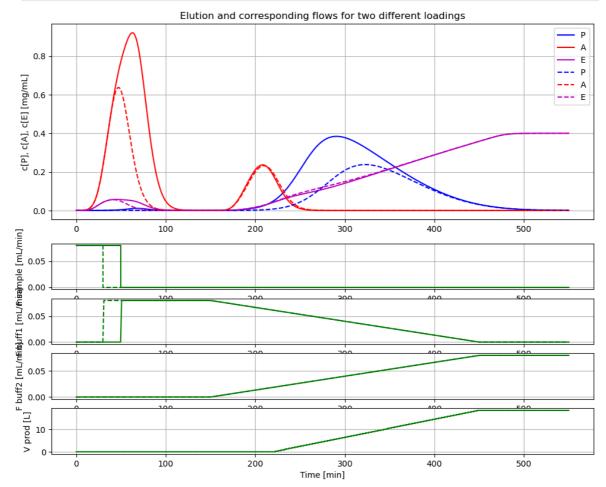

Note that the salt concentration deviates slightly from the linear increse between time 50 to 100. This is due to ion interaction with P and A in the column. This is phenomenon can also be seen in real data. The ion-salt concentration is scaled with factor 0.05 to get comparable concentrations to P and A.

I have here simulated time 150 of adsorbtion and then started elution. Here is time counted as zero at time of start of elutions. Not sure how long Jonas simulated to get steady state before he did elution.

```
In [15]: # More complete visualization of the elution phase and the different flows
    newplot(title='Elution and corresponding flows for two different loadings', plot
    par(stop_adsorption=50); simu(550)

# Simulation with changed parameter t2
    par(stop_adsorption=30); simu(550)

# Reset changed parameter
    par(stop_adsorption=50)
```

Here a diagram that shows the peaks at the outlet as shown in the previous diagram. Below the flow rates of the three different sorces. Here time is 0 at start of adsorbtion and elution starts at time 150.

Automatic pooling based on UV-mmeasurement is tested in another notebook.

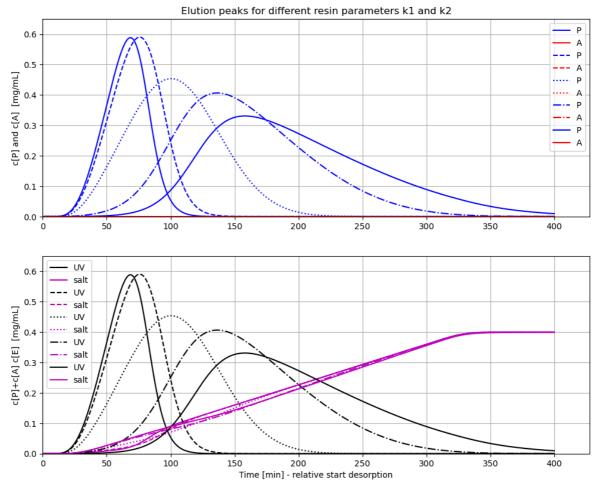

Change of resin properties

```
In [16]: # Elution of the column
newplot(title='Elution peaks for different resin parameters k1 and k2', plotType
# Sample
par(P_in=1, A_in=0.0, E_in=0)
```

```
# Operation
par(E_in_desorption_buffer=8)
par(LFR=12.0, start_adsorption=0, stop_adsorption=50, start_desorption=150, stat

# Simulations
par(k1=0.05, k2=0.50); simu(550)
par(k1=0.05, k2=0.25); simu(550)
par(k1=0.05, k2=0.05); simu(550)
par(k1=0.25, k2=0.05); simu(550)
par(k1=0.50, k2=0.05); simu(550)

# Adjust diagrams
ax1.set_ylim([0, 0.65])
ax2.set_ylim([0, 0.65])
plt.show()
```

The results are the same af Figure 17 in [1].

Summary

Three important diagrams Figure 13, 14 and 17 in the original report [1] were reproduced and the implementation in Modelica used here is considered validated.

The model is now extended with an improved parametrization of the column that match the industrial practice.

Acknowledgement

The author thank Karl Johan Brink for sharing his know-how of chromatography operation. He has especially given input to how to parametrize the model in terms often used in the industrial practice.
